This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- This work aims to incorporate bottom boundary layer effects forced by single and two wave motions.
- The fluid velocities and pressure are decomposed into two components: potential and rotational.
- A coupling term between the potential and rotational component has shown a significant improvements of the model results.
- The numerical cost for the model is an order of magnitude less compared to other models while obtaining the same results.
- The bottom shear stress under solitary wave is calculated using the rotational velocity and the sign change is captured.
