Abstract

Rainfall time series of high temporal resolution and spatial density are crucial for urban hydrology. The multiplicative random cascade model can be used for temporal rainfall disaggregation of daily data to generate such time series. Here, the uniform splitting approach with a branching number of 3 in the first disaggregation step is applied. To achieve a final resolution of 5 minutes, subsequent steps after disaggregation are necessary. Three modifications at different disaggregation levels are tested in this investigation (uniform splitting at $\Delta t=15$ min, linear interpolation at $\Delta t=7.5$ min and $\Delta t=3.75$ min). Results are compared both with observations and an often used approach, based on the assumption that a time steps with $\Delta t=5.625$ min, as resulting if a branching number of 2 is applied throughout, can be replaced with $\Delta t=5$ min (called the 1280 minutes approach). Spatial consistence is implemented in the disaggregated time series using a resampling algorithm. In total, 24 recording stations in Lower Saxony, Northern Germany with a 5 minute resolution have been
