Abstract

We study the norm approximation to the Schrödinger dynamics of N bosons in \mathbb{R}^3 with an interaction potential of the form $N^{3\beta-1}w(N^\beta(x-y))$. Assuming that in the initial state the particles outside of the condensate form a quasi-free state with finite kinetic energy, we show that in the large N limit, the fluctuations around the condensate can be effectively described using Bogoliubov approximation for all $0 \leq \beta < 1/2$. The range of β is expected to be optimal for this large class of initial states.

Résumé: Nous étudions l'approximation en norme de la dynamique de Schrödinger de N bosons dans \mathbb{R}^3 interagissant via un potentiel de la forme $N^{3\beta-1}w(N^\beta(x-y))$. En supposant qu'au temps initial les particules en dehors du condensat forment un état quasi-libre d'énergie cinétique finie, nous montrons que, dans la limite où N devient grand, les fluctuations autour du condensat peuvent être effectivement décrites par l'approximation de Bogoliubov, et ce pour tout $0 \leq \beta < 1/2$. On conjecture que cette restriction sur β est optimale pour cette classe d'états initiaux.

Keywords: Quantum dynamics, Mean-field limits, Bogoliubov theory
