## Abstract

Our aim is to simulate a nonlinear system of ODEs describing the flow in smectic liquid crystals. The nonlinear system is first linearized. We present a direct approach to compute the exact analytic solution of this linear system and use this solution as a starting profile in the MATLAB package `bvpsuite2.0` to obtain the approximate solution to the nonlinear system. Although, the solution of the nonlinear system has steep boundary layers and therefore is difficult to resolve, we demonstrate that `bvpsuite2.0` can cope with the problem and provide an approximation with reasonable accuracy.

## 1 Introduction

Nematic liquid crystals consist of rod-like molecules that have preferred local average direction; this direction is usually characterized by a unit vector  $\mathbf{n}$ , called the director. Smectic liquid crystals (SmA) tend to have more order: they occur when the molecules are arranged in parallel layers with the director parallel to the unit layer normal  $\mathbf{a}$  as displayed in Figure 1.
