10 **Abstract**

11 We combined the RUSLE model with a calibrated sediment delivery ratio SDR to obtain a  
12 simulated suspended sediment yield, which is compared with the observed ones founded in 42  
13 catchments of the biggest and important dams of Morocco. The comparison allowed us to  
14 understand areas where the model can give suitable results and also understand the factors  
15 controlling the suspended sediment yield. The analysis of the long-term observed values of  
16 sedimentation in all selected reservoirs in Morocco shows an annual mean Sediment Yield (SY)  
17 of 1.51 million m<sup>3</sup> with a standard deviation of 2.09 million m<sup>3</sup>·year<sup>-1</sup>. A very strong positive  
18 relationship was determined between sedimentation in reservoirs and the corresponding drainage  
19 area ( $R^2 = 0.77$ ); reservoirs with high sediment yield are those characterized by large drainage  
20 areas. We converted the sediment yield values into Suspended Sediment Yield (SSY) ( $t \cdot ha^{-1} \cdot year$   
21 <sup>1</sup>) in order to better understand its spatial distribution all over the studied watersheds. The average  
22 founded is  $6.40 t \cdot ha^{-1} \cdot yr^{-1}$ , with the highest values observed in the North of the country dominated
