### **ABSTRACT**

Over the past decade, a number of methods have emerged for inferring protein-level transcription factor activities in individual samples based on prior information about the structure of the gene regulatory network. We discuss how this has enabled new methods for dissecting trans-acting mechanisms that underpin genetic variation in gene expression.

### **KEYWORDS**

gene regulatory networks; transcription factor activity; systems genetics; QTL mapping

### **FUNDING**

This research was funded by National Institutes of Health grant R01HG003008.

### **HIGHLIGHTS**

- Large-scale compendia of parallel genotype and molecular phenotype data are creating new opportunities for dissecting regulatory networks.
- The activity of transcription factors can be inferred by integrating prior information about their DNA binding specificity with genome-wide information on transcript abundance.
- Treating inferred transcription activity as a quantitative trait provides a powerful strategy for mapping *trans*-acting genetic determinants of gene expression variation.
- Linear regression methods can be used to perform sophisticated transcription-factor-centric analyses, *e.g.*, mapping genetic polymorphisms associated with co-factors that modulate the responsiveness of the cell to perturbation.
