Highlights

- Cancer is characterised by dysregulation of intracellular signalling network
- Probing networks of protein-protein interactions demands new highly selective tools
- Scaffold-based binding proteins are highly selective from individual protein domains
- Such tools offer exciting potential to explore protein-protein interaction in cancer

Abstract

Cancer is frequently characterised by dysregulation of the cellular signalling processes that govern proliferation, survival and attachment. Understanding such dysregulation continues to present a challenge given the importance of protein-protein interactions in intracellular processes. Exploring this protein-protein interactome
