This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- Deficits in several cognitive domains predicts disability in quality of life, and social, occupational, and global functioning
- Self-perceived daily functioning is primarily associated with executive functioning and global cognition
- Longitudinal psychosocial functioning outcomes are related to executive functioning, attention, and memory
- Older age and greater depression symptom severity appear to enhance the negative relationship between cognitive deficits on psychosocial functioning
