Abstract

An ultrasensitive label-free photoelectrochemical (PEC) immunosensor with high visible-light activity was developed for quantitative detection of amyloid β -protein ($A\beta$) by cross-linking anti- $A\beta$ antibody onto the Ag_2S sensitized $\text{SnO}_2/\text{SnS}_2$ nanocomposites. Specifically, SnO_2 with flower-like porous nanostructure was innovatively applied in PEC immunosensor as a basal material. It could form a heterostructure with SnS_2 , which brought about the sensitization of SnO_2 and enhanced the separation of photogenerated electrons and holes. Moreover, Ag_2S was in-situ growth on the surface of $\text{SnO}_2/\text{SnS}_2$, which further enhanced the photocurrent response significantly. Therefore, $\text{SnO}_2/\text{SnS}_2/\text{Ag}_2\text{S}$ could form stepwise band-edge structure, which benefited the light harvesting and provided a good foundation for sensor construction and detection. Under optimal conditions, the PEC immunosensor was used to detect the content of $A\beta$ and exhibited a wide linear concentration range
